Winter Quarter 2017
Preface

This project idea comes from my experience as a single data person at a startup. Without the properly sized team, it is easy to get bogged down with ad-hoc query requests leaving less time for more critical projects. More likely, some ad-hoc query requests get rejected or pushed on the backburner for lack of resources. In my experience applying for jobs, I have found a lot of jobs for “data analyst” that mainly consist of retrieving data via sql queries. Our topic will focus on automating this process. Our paper will work towards the goal of such automation. Interesting future work could be done in combining these results with automatic data visualizations.
Abstract

We investigate avenues of using natural english utterances - sentence or sentence fragments - to extract data from an SQL, a narrower inspection of the broader natural language to machine language problem. We intend to contribute to the goal of a robust natural language to data retrieval system.

1. Acknowledgements

We would like to express our sincere gratitude for all the developers who are creating these powerful and useful libraries and keeping them open source. Most specifically, we will heavily utilize python’s nltk package as well as Stanford’s CoreNLP. Quepy has also provided a benchmark.

We are very grateful to all of the researchers and journals who have laid the theoretical foundations for this project. Our bibliography shows all the resources we used in the creation of this project.

We would also like to thank Santa Clara University for providing us access to research papers such as those published by ACM. The level of detail these papers provided has been invaluable to our understanding of the topic. Santa Clara has also provided us with a usable meeting place to discuss our project in person.

Last, but not least, we are deeply grateful to our project instructor and advisor, Prof. Ming-Hwa Wang, for his continued support and encouragement.
2. Introduction

2.1 Objective

The objective of our project is to generate accurate and valid SQL queries after parsing natural language using open source tools and libraries. Users will be able to obtain SQL statement for the major 5 command words by passing in an English sentence or sentence fragment. We wish to do so in a way that progresses the current open source projects towards robustness and usability.

2.2 Problem Statement

This project makes use of natural language processing techniques to work with text data to form SQL queries with the help of a corpus which we have developed. En2sql is given a plain English language as input returns a well structured SQL statement as output.

2.3 Existing Approaches

The existing approach is to generate the query from the knowledge of SQL manually. But certain improvement done in recent years helps to generate more accurate queries using Probabilistic Context Free Grammar (PCFG). The current implemented standard is QuePy [10] and similar, disjoint projects like them. These projects use old techniques; QuePy has not been updated in over a year. The QuePy website [10] has a interactive web app to show how it works, which shows room for improvement. QuePy answers factoid questions as long as the question structure is simple. Recent research such as SQLizer [7] presents algorithms and methodologies that can drastically improve the current open source projects. However, the SQLizer website does not implement the natural English to query aspect found in their 2017 paper. We wish to prove these newer methods.

2.4 Proposed Approach

The proposed approach aims to use knowledge of SQL to create a corpus which will help to identify SQL command words i.e SELECT, INSERT, DELETE, UPDATE and map the tokens with appropriate POS. Word similarities will be calculated with the input tokens to the database schema (table names, column names, data) to insert table names, column names, and data comparisons into the query.
2.5 Scope of Investigation

We will be implementing SELECT, INSERT, DELETE, UPDATE query and WHERE clauses. We hope to implement more clauses such as join, aggregate, order by, limit, etc but cannot commit to these more challenging due to their added complexity and time constraints.

The research will start by focusing on statements (“get / find number of employees”) and then extend to questions (“Who is Bob?”). The statements are easier as it gives more keywords to interpolate the SQL query structure.

There are many relations databases. While their SQL syntax is similar, it can differ for more complicated queries. We will focus on MySQL as it is an open source database with a large user base.
3. Theoretical Bases and Literature Review

3.1 Theoretical Background of the Problem

The problem we address is a subcategory of a broader problem; natural language to machine language. SQL is opportunistic for its distinctive, high level language and close connection to the underlying data. We utilize these characteristics in our project.

SQL is tool for manipulating data. To create an system which can generate a SQL query from natural language we need to make the system which can understand natural language. Most of the research done until now solve this problem by teaching a system to identify the parts of speech of a particular word in the natural language which is called tagging. After this the system is made to understand the meaning of the natural query when all the words are put together which is called parsing. When parsing is successfully done then the system generates a SQL query using proper syntax of MySQL.

3.2 Related Research of the Problem

Following corpus development which was helping computer identify tables and columns name. Using experience and after learning a pattern it can learn even following type of tables. E.g. emp_table, emp, emp_name. The parsing tree can also be build using a PCFG. PCFG uses probability to build a most relevant tree from the many options created.

3.4 Our Solution to the Problem

The system will deploy a natural language understanding component that identifies speaker intents and the variables needed for a specific intent example. Our solution uses the technique presented in the paper but also enhance it because of the corpus which we are developing which will be schema specific.
4. Hypothesis

If we create a corpus with perfect mapping of schema we will be able to identify the major elements properly. We are trying to create our own syntactic parser which will help us to give the query matching more accurately.

Also parser will be able to identify the types of joins in the query from the natural english text like inner join, outer join and even the self joins.

The focus will be on making queries with the various sql functions like count, aggregate, sum etc and even complex queries with like, in, not in, order by, group by etc.
5. Methodology

5.1 Data Collection

With the domain level knowledge of SQL we will create a corpus which will contain words which are synonymous the SQL syntax to SELECT, LIMIT, FROM, etc. This is common among the open source projects we have seen. Many of the open source projects we have inspected use such keywords, thus coming up with a generous keyword corpus will be easy. If our english to keyword mapping results are not desirable, we may use an online thesaurus api. A MySQL database will be constructed with data from the public Yelp SQL Database [13]. We chose the yelp dataset because it is fairly large, has a good amount of tables, and we have some domain level knowledge about Yelp already. This data will be used as a corpus and for testing. The corpus will be constructed from the table names, column names, table relationships, and column types. The database corpus will be used in an unsupervised manner to keep the program database agnostic. A set of substructure queries will be used as a starting point for the queries. The natural language tokens will be matched to these.

5.2 Solution Structure

5.2.1 Algorithm design

Following will be our algorithm

1. Scanning the database: Here we will go through the database to get the table names, column names, primary and foreign keys.
2. Input : We will take a sentence as a input from the user (using input.txt)
3. Tokenize and Tag : We will tokenize the sentence and using POS tagging to tag the words
4. Syntactic parsing : Here we will try to map the table name and column name with the given natural query. Also, we will try to identify different attributes of the query.
5. Filtering Redundancy : Here we will try to eliminate redundancy like if while mapping we have create a join requirement and if they are not necessary then we remove the extra table.
6. Query Formation : Here we will form a complete SQL query based on MySQL syntax.
7. Query Execution : Here we will execute the query on database to get results
Program design:

5.2.2 Language

Our project uses Python 3.6. Python has many readily available and proven open source libraries. All our required libraries support Python 3.6.

5.2.3 Tools used

**NLTK3** library for python will be used for input stemming. This library serves as a toolkit for computational linguistics. Following is a list of the modules we will be using.

Token module provides basic classes for processing individual elements of text, such as words, or sentences. Nltk tokenizer is used to tokenize incoming sentences. The wordnet lemmatizer and porter stemmer is used parse the input’s base words for comparison.

Stanford’s part of speech tagger [14] is used to tag the input natural language query.

To connect to the mysql database, we used PyMysql (pymysql). While it is not optimized out of the box, it can be optimized with additional tools. We chose it because it is written in python and supports python 3.6. Being written in python, it can be installed with python’s pip packaging system. We use MySql for this project for its ease of use, expressive querying language, open sourceness, and many python packages to work with it.

5.3 Output
The program with output a structure SQL query that runs on the database and attempts to answer the input question or statement. The output is displayed to stdout as well as into output.txt.
5.4 Output Testing

To test our code we will first create a schema specific corpus which will contain data related to table, column name, column data. Another corpus will contain data related to query command SELECT. And then we will be giving it a general natural language statement to test it. It will take input of the natural language and then will make use of the two corpuses and thus will output a SQL query. We will take the output query and run it against the MySQL Yelp Database, testing the runnability of the query. After it runs, we will take the resulting data and compare it to our expected results. For the last test, we will inspect the query for correctness making sure a wrong query does not return the correct data. We will need to construct a set of natural english with expected output pairings. If the query can pass the first two automated tests, then it will need to be hand inspected for correctness. If all three tests pass, the query is correct. With this testing methodology we will construct an accuracy for the program.
6. Implementation

System Design

We propose a system which looks to overcome the shortcomings of existing system that gets a natural language sentence as an input, which is then passed through various phases of NLP to form the final SQL query.

1. Tokenize and Tag
   The input natural language query gets split into different tokens with the help of the tokenizer ,word_tokenizer, from 'NLTK' package. The tokenized array of words is tagged according to the part-of-speech tagger using the Stanford POS tagger [14]. All processes following this step use these tagged tokens for processing. We also implement

2. Analyze tagged tokens
   Based on the tagged tokens of earlier step, the noun map and verb list is prepared through one iteration over the tokens. The tokens corresponding to aggregate functions are also mapped with their respective nouns using a pre-created corpus of words. The decision whether the natural language statement represents a data retrieval query (SELECT) or a DML query (INSERT, UPDATE, DELETE) is taken at this stage with the help of certain ‘data arrays’ for denoting type of query. For example, when words like 'insert' and its certain synonyms appear in the input, the type of query is 'INSERT' and so on. In any type of query, the tentative tags 'S' (SELECT), 'W' (WHERE), 'O' (ORDER BY) are mapped to the nouns indicating the clauses to which they belong. For this, we have designed 'data dictionaries' for different clauses. These data dictionaries consist of the token-clause term pair, for e.g. aggregate clause data dictionary is "number": "COUNT", "count": "COUNT", "total": "SUM", "sum": "SUM", "average": "AVG", "mean": "AVG". Thus, if any of these tokens is encountered, it is likely to have aggregate clause and accordingly the nouns are tagged with the clause tag.

3. Map to table names and attributes
   Using the noun map and verb list, the table set is prepared, which will hold the tables that are needed in the query to be formed. This is based on the fact that the table names are either nouns or verbs. The noun map is used to find the attributes which are needed in the final query. The attributes, the table associated with the attribute and the clause tag are stored in an attribute-table map which is used in the final stage of query formation. This is done using the string matching algorithm that we have implemented in our system. The words in the input sentence need not exactly be as they are in the database. The stemmer and lemmatiser are applied on the words before they are matched using our string matching algorithm. The data obtained during this step i.e. table set and attribute-table map, is most likely to be in the final query, however, it might be refined later.
4. Filter redundancy and finalize clauses of the query

Using the various data dictionaries defined, the system has already decided which clauses are likely to exist in the final query and has mapped the data to the clauses. But, some of the data has to be finalized at this stage. The data related to GROUP BY and HAVING clause is collected using the previous data and the basic rules of SQL. For example, if aggregate function is compared to a constant, i.e. 'MAX(salary) > 40000', then 'HAVING' clause has to be used instead of 'WHERE' clause.

As mentioned in the earlier step, the refinement of data must be done. Here, the redundant tables and attributes are removed using some filter algorithms. For example, one of the algorithm filters the table and their corresponding attributes which are a subset of some other table in table set. i.e. if table set has [table1, table2] and table1 has attributes [a1, a2] and table2 has [a1, a2, a3] after the previous steps, then table2 is enough to represent all the attributes required and hence table1 is removed. There are various other algorithms applied in order to filter the results and finalize the table set and table-attribute map.

5. Form the final query and execute

Currently, as our system handles only MySQL queries, the templates used for the query formation will be according to the MySQL syntax. According to the type of query selected in the second stage of the process (Analyze tagged tokens), the appropriate template is chosen. The template is selected from the following:

1. For data retrieval queries (SELECT):
   1.1. SELECT <select clause>
       FROM <tables>
       WHERE <where clause> ORDER BY <order by clause> GROUP BY <group by clause> HAVING <having clause> LIMIT <limit clause>.

2. For data manipulation queries (INSERT, UPDATE, DELETE):
   2.1. INSERT INTO <insert clause> VALUES <values clause>
   2.2. UPDATE <update clause> SET <set clause> WHERE <where clause>
   2.3. DELETE FROM <delete clause> WHERE <where clause>

Based on the data about various clauses collected from earlier steps and the information about attributes and tables stored in the attribute-table map, the final query is formed by filling in the information into the appropriate template. Depending on the clause data collected from earlier steps, corresponding <> are filled. Depending on the relation between multiple tables, the decision of INNER JOIN or NATURAL JOIN is taken. For example, if there are two tables. If these two tables have one common attribute and is named the same in both, then there is NATURAL JOIN between the tables. But if the common attribute is named differently in the two tables, then there is INNER JOIN
between the tables. The final query is as shown in Fig 2.

Figure 2: Algorithm with example
7. Data Analysis and Discussion

7.1 Dataset
We will create our own corpus by scanning the schema for the table name, column name, column types, key relations, and the data. This will be schema specific dataset. Another corpus will contain all the necessary elements to build the query. It will contain probable words for Select, Insert, Delete, Where which will help to form a query based on the input. We also use Stanford’s POS corpus \[14\] ans the WordNet corpus via nltk.

7.2 Setup
For implementing En2SQL you will need following packages. Python3, NLTK, pymysql, Stanford’s POS Tagger \[14\], Oracle MySql, and the Yelp SQL Dataset \[13\]. First you will need to set up a user for the MySQL database, then upload the Yelp SQL data to the database. We include the POS tagger with the code. Run the requirements.txt (via pip3) file to install the python package requirements (nltk and pymysql). Update the database connection details in the db.config.py file. Input natural language queries into input.txt, one per line. Run the main.py file.

7.3 Results and Analysis
The corpus that can be used to test our system is not readily available and is dependent on a database. Hence, we have tested our system on a synthesized corpus of natural language statements related to a bank and a university database. The university and bank database consists of 11 and 6 tables respectively. However, system can work on any complex database. The natural language statement has to be a single sentence. The system has been evaluated on a corpus of around 75 natural language statements of university database and around 50 related to bank database. The accuracy of the system is found out to be around 86%. The system gives the same SQL query as the output when the same natural language statement is represented in different ways. If the system fails to generate SQL query corresponding to any natural language statement, an error message is displayed. These are a few results given by the system on the university corpus:

1. Find the student name where instructor name is ‘Crick’.

   SELECT DISTINCT student.stud name
FROM instructor
INNER JOIN advisor
ON instructor.ID = advisor.inst ID
INNER JOIN student
ON student.ID = advisor.stud ID
WHERE instructor.name = 'Crick'

In this database, the tables 'student' and 'instructor' are linked through the table 'advisor'. So, we can see that this query deals with multiple tables which are joined by INNER JOIN.

2. Find all student name whose credits are between 90 and 100 and department name is 'Finance' or 'Biology'.

SELECT DISTINCT student.stud name
FROM student
WHERE ( student.tot cred BETWEEN '90' AND '100' ) AND ( student.dep name = 'Finance' OR student.dep name = 'Biology' )

The above query showcases multiple conditions within the WHERE clause. This query also involves use of BETWEEN clause and logical clauses like AND, OR.

3. List all student names whose credits are 50 in decreasing order of credits.

SELECT DISTINCT student.stud name
FROM student
WHERE student.tot cred = '50'
ORDER BY student.tot cred DESC

Another type of query is the one involving sorting its result based on some attribute. For this purpose, the query uses the ORDER BY clause to sort the results in decreasing order.

4. Give the department name where maximum salary of instructor is greater than 50000.

SELECT DISTINCT instructor.dep name
FROM instructor
GROUP BY instructor.dep name
HAVING MAX(instructor.salary) >'50000'
In SQL, when an aggregate function is compared to constant, like in this case maximum of salary is compared to 50000, then the query involves use of HAVING clause instead of a WHERE clause. Also, whenever HAVING is used, the results are supposed to be grouped by the attributes in the SELECT clause.

5. Give the department name where salary of instructor is greater than average of salary.

```sql
SELECT DISTINCT instructor.dep name
FROM instructor
WHERE instructor.salary >
( SELECT AVG(instructor.salary)
FROM instructor )
```

This query showcases a special case of nested queries. Whenever an attribute is compared to the result of an aggregate function, i.e. in this case salary greater than average of salary, we have to use nested query.

6. Find the course taught by Crick.

```sql
SELECT DISTINCT teaches.course id
FROM teaches
NATURAL JOIN instructor
WHERE instructor.name = 'Crick'
```

Till now, we have seen cases in which an attribute associated to the value is mentioned in the natural language statement. In this case, we handle cases where attribute is not mentioned. We find out the most appropriate attribute for the given value.

7. 
   a. Publish in alphabetic order the names of all instructors.
   b. Give names of all the instructors in alphabetical order.
   c. Give instructors names in ascending order.

```sql
SELECT DISTINCT instructor.name
FROM instructor
ORDER BY instructor.name ASC
```

As seen in this example, there can be multiple ways of representing the same natural language statement. The system gives the same SQL query as the output when the same natural language statement is represented in different ways.

8. Insert a student whose id is 5, name is Josh, department name is Physics and credits are 150.
In addition to the data retrieval queries, our system also provides a natural language interface to insert data into the database. Other DML queries such as UPDATE and DELETE are also provided by the system.

7.4 Limitations

The following are some of the types of inputs that are not presently handled by our system.

1. Find the capacity of the classroom number 3128 in building Taylor

```sql
SELECT *
FROM classroom
WHERE classroom.capacity = '3128'
AND classroom.building = 'Taylor'
```

In this particular example, the system fails to decide whether to take 'capacity of classroom' or 'classroom number' as an n-gram. Hence, the mapping fails.

2. Who teaches Physics?

```sql
SELECT *
FROM department
WHERE department.dep name = 'Physics'
```

In this example, the implicit query module of our system is able to map Physics to 'department name' attribute from table 'department'. But it fails to identify that 'who' refers to a person (an instructor).

Our system struggles with column value references in the natural language. It can hang trying to find the match to the column value to a word in the schema. This is addressed in section 8.
7.5 Abnormal Case Explanation:

1) Some input table name, column name consist of underscore, short forms due to which it becomes unusual and hard for it to distinguish amongst stop word, normal word. So we have to add it to corpus or explicitly mention it before using it. The accuracy while generating queries shows a minute fluctuations.

2) Some English statements are very less informative. For example: Who is Bob? This question if asked for a huge database creates an ambiguity to find the correct answer. It sometimes gives and correct output and sometimes it gives a vague output.
8. Conclusions and Recommendations

Summary and Conclusions:

This project has given us a great opportunity to come up with a solution for writing tedious queries. This project though helps resolving basic queries but with time it can made powerful to handle complex queries, normalization and also can be extended for nosql. We were able to learn and implement NLTK, cosine, tf-idf of python3. We have got accuracy around 30-50% in basic queries.

Recommendations for future studies:

We wanted to analyze the custom bag of words using LSTM based RNN network and verify how the performance of system changes. Instead of using trivial NLP techniques like NLTK, custom corpus we wanted to use Stanford NER library which contains all the known words with tags.

There are many steps to improve the work we have done. A using thesaurus to match input tokens not only to the table and column names but their synonyms as well would greatly increase our accuracy and chances a natural language token would be matched to a correct corpus name.

The next changes to be implemented are better column value matching. Currently the system has a hard time matching an input token to a column value (as opposed to a column or table name). After parsing all table and column names, we can use the LIKE MySQL syntax with %% to find column values that contain the input token. We would only evaluate nouns in this case. We could count the number of rows that contain the token and use the column with the highest count.

We have not addressed abbreviations in this project. Simply, a corpus of English abbreviations would be used to map from common words to abbreviations and vise versa.

This project does not allow for user input after a failed query. The future scope of this project will look at prompting the user for correct input token to corpus token mappings to build up a thesaurus on the database and improve its performance. It also does not address non-natural column or table names, studentName or student_name for example. In this case we could split on cammel case and underscores respectively add keep then nouns in the new word set. The input tokens can be matched against the set of words.

Before the code is useful, tests need to be written and the coding style needs to be updated.
